TITLE: Thermodynamics of dielectric relaxation processes in liquids.

SOURCE: AN SSSR. Zhurnal fizicheskoy khimii, v. 37, no. 5, 1963, 1083-1088

TOPIC TAGS: relaxation processes, phenyl O-hydroxybenzoate, phenyl o-acetoxybenzoate

ABSTRACT: A previous study (A. V. Komandin, L. I. Sizov and B. D. Shimit, Zh. Fiz. Khimii, 37, 764, 1963) was made on the dependence of temperature upon the penetration of phenyl o-hydroxybenzoate and phenyl o-acetoxybenzoate at various frequencies of external electric field in a liquid and a supercooled media. The present work is concerned with the investigation of the dispersion penetrations of these compounds at several temperatures. From the results obtained in both investigations, the main thermodynamic functions characterizing the dielectric relaxation processes in the liquids are calculated. The dispersion of the dielectric constant of phenyl o-hydroxybenzoate at 10, 15 and 20C, and

Card 1/2

L 9903-63
ACCESSION NR: AP3000418

of phenyl o-acetoxybenzoate at 55 and 42C in the supercooled state has been determined. A linear relationship between log Tau and 1/T has been established for both compounds and their corresponding derived equations. A detailed explanation and calculations are given in the discusssion of results. Orig. art. has: 7 equations, 7 tables and 3 graphs.

TITLE: Device for checking the working substance in a closed hydraulic system. Class 72, No. 183626

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 13, 1966, 153

TOPIC TAGS: hydraulic device, hydraulic engineering, hydraulic equipment

ABSTRACT: An Author Certificate has been issued for a device for checking the working substance in a closed hydraulic system. It consists of a main pump, a booster tank, and pressure signaling devices mounted on the pressure and suction lines of the main pump and connected to the closed hydraulic system. To automatically compensate for working-substance losses in the hydraulic system the signaling device mounted on the pressure line actuates a hydraulic pumping cylinder to replace losses, and the signaling device mounted on the suction line turns it off. The pumping cylinder is equipped with a terminal switch which signals the amount of liquid fed into the system. [SA]

TITLE: The Laws Governing the Outflow of a Liquid Through a Small Orifice From Containers Having the Shape of Bodies of Revolution (Zakony istecheniya zhidkosti cherez maloye otverstiye iz sosudov, imeyushchikh formu tel vrashcheniya)

PERIODICAL: V sb.: Mekhanika (MVTU, Vol 50). Moscow, Oborongiz, 1956 pp 237-244

ABSTRACT: The usual formula $v = \mu\sqrt{2gz}$, containing the variable height z and the constant orifice velocity coefficient μ, is employed to express the velocity of the outflow of a heavy liquid through a small orifice of arbitrary form, located near the bottom of a vessel, in the absence of any compensating inflow. Assuming incompressibility, the Author obtains the time t of complete discharge in the form of an integral, the evaluation of which is accomplished by means of a relationship containing μ between t, z, and the initial height of the liquid level for certain special cases. There are no numerical examples.

TITLE: Solution of the Poincare linear system in the case of a zero root of the characteristic equation

SOURCE: IVUZ. Matematika, no. 3, 1963, 153-157

TOPIC TAGS: periodicity, differential equation, quasi-linear system, characteristic equation, zero characteristic root, pure imaginary root, characteristic root

ABSTRACT: The author obtains an additional condition for periodicity. When this is satisfied, there exists a periodic solution of the pseudo-linear system (see Enclosure 1) in the presence of purely imaginary roots and one zero root of the characteristic equation of the system. This condition is simple to verify since it can be expressed in terms of the coefficients of the given system, and it is convenient for practical computations. Orig. art. has: 28 formulas.

TITLE: Spin ordering and magnetocrystalline anisotropy in single crystals of $BaCo_xFe_{18-x}O_{27}$ ferrites

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 50, no. 3, 1966, 595-604

TOPIC TAGS: ferrite, single crystal, magnetic anisotropy, neutron diffraction, nuclear spin, Curie point, temperature dependence, spin wave theory

ABSTRACT: This is a continuation of earlier work by the authors (ZhETF v. 46, 1985, 1964). In this paper new data are presented on the magnetic anisotropy energy of the ferrite system under discussion. The crystals were grown by the Verneuil method and were the same as

Card 1/2

L 2[illegible]-66
ACC NR: AP6010980

used in the earlier investigation. In view of the fact that the ferrites investigated exhibit various types of magnetic anisotropy at low temperatures, the authors used a neutron diffraction method to investigate the influence of the cobalt ions on the positions of the spin ordering axis in these crystals in the temperature range from 77K to the Curie temperature. The temperature dependence of the magnetic anisotropy constants was investigated in the same range of temperatures and compared with the theory. The same samples were used to obtain neutron diffraction patterns as were used in the investigation of the magnetic anisotropy. The results show that the spin directions coincide with the directions of the total magnetization vectors of the crystals. The data also indicate that the experimental results can be fully reconciled with a theoretical formula deduced by Ye. A. Turov from the phenomenological theory of spin waves (Fizicheskiye svoystva magnitouporyadochennykh kristallov [Physical Properties of Mangetically Ordered Crystals], AN SSSR, 1963), without need to make allowance for any particular structure model. TITLE: The effect of particle size on extinction in neutron diffraction.

SOURCE: Kristallografiya, v. 10, no. 3, 1965, 423-424

TOPIC TAGS: powder metallurgy, particle size, neutron diffraction

ABSTRACT: The effect of powder size on the magnitude of extinction was determined experimentally. The sample consisted of $BaCo_{1,0}Fe_{1,0}{}^{2+}Fe_{16}{}^{3+}O_{27}$ ferrite powder pressed into a thin-walled aluminum cylinder with a diameter of 15 mm and 30 mm high. The powder was obtained by the mechanical grinding of crystals and subsequent sieving with screens of different mesh. A total of six samples of different particle size were prepared. The two most intense reflections (1010 and 1120) were used. The first is basically of magnetic origin while the second is both magnetic and nuclear. The exposure was made at room temperature using a two-coordinate neutron diffractometer installed on the radial channel of the reactor. The variation in the intensity of reflections was due to extinction. The effect of other factors is estimated as less than 1%. The experimental data were used to plot curves which

Card 1/2

L 58367-65
ACCESSION NR: AP5013724

show that the extinction effect was small in sample No. 3 (approximately 1%) and was absent in sample No. 4.

TITLE: Neutron diffraction study of the magnetic structure of hexagonal ferrites of the Co_xW system

SOURCE: AN SSSR. Doklady, v. 168, no. 1, 1966, 90-93

TOPIC TAGS: neutron diffraction, ferrite, cobalt compound, barium compound, iron compound, magnetic structure, crystal, polycrystal, nuclear spin

ABSTRACT: In order to determine the spin ordering in ferrites of the Co_xW system ($BaCo_x^{2+}Fe_{2-x}^{3+}Fe_{16}^{3+}O_{27}$), the authors carried out a neutron diffraction analysis on single and polycrystals with compositions x = 0, 0.5, 1.0, 1.5, and 1.75, in the range from 77 to 770°K. The correct values of the magnetic contributions to the diffraction pattern and absolute values of the saturation magnetization were obtained. The model of spin ordering in its general features and the angle between

Card 1/2 UDC: 539

L 29785-66
ACC NR: AP6015089

the spin axes and axis c were determined by analyzing the neutron diffraction patterns of polycrystalline specimens. Additional information was obtained from observations of the temperature dependence of the intensity of magnetic reflections from single crystal specimens. The paper was presented by Academician Belov, N. V., 20 Sep 65. Authors thank T. M. Perekalina and R. A. Vaskanyan for providing the specimens, Yu. Z. Nozik for constant interest in the work and useful suggestions, and Prof. J. Bacon for a helpful discussion of the results. Orig. art. has: 2 figures and 2 tables.

TITLE: Heating Camshafts for Tempering by Higher Frequency Currents (Nagrev pod zakalku raspredelitel'nykh valov tokami povyshennoy chastoty)

PERIODICAL: Avtomobil'naya promyshlennost', 1958, Nr 8, pp 37-38 (USSR)

ABSTRACT: For the induction heating of camshafts for tempering, frequencies of 8,000 - 10,000 c instead of the normal 2,000 - 3,600 c offer distinct advantages. The 2,000 c, 200 kw generator usually feeds two tempering machines with a total production of 36 shafts per/hour and a power consumption of 3.25 kw hrs a shaft. The 3,600 c, 200 kw generator has a capacity of up to 60 shafts p/hr and a power consumption per shaft of 1.9 kw/hr. An 8,000 c, 175 kw generator, however, has a capacity of up to 80 shafts p/hr and a power consumption of 1.6 kw hrs per shaft. The normal water-screened inductor can not be used with 8,000 c generators since uneven heating of the cams occurs. Instead, an inductor with electro-magnetic screening is used, produced by the Ural'skiy and Moskovskiy avtozavody (Ural and Moscow Motor Vehicle

Card 1/2

Plants). Soviet industry does not produce 10,000 c high frequency generators, so the upper frequency limit at present is 8,000 c, at 100 kw power. The use of tube generators is not advisable since they cause uneven heating. There is 1 table and 3 Soviet references.

TITLE: Application of a microwave method for measuring electron concentrations exceeding the critical concentration

SOURCE: Zhurnal Tekhnicheskoy fiziki, v.34, no.6, 1964, 961-964

TOPIC TAGS: plasma, plasma physics, microwave plasma, electron concentration, recombination phenomena, neon

ABSTRACT: The authors describe the microwave method for measuring electron concentrations exceeding the critical concentration $m\omega^2/4\pi e^2$ employed by L.Goldstein and T.Sekiguchi (Phys.Rev.109,625,1958), T.Sekiguchi and R.C.Herndon (Ibid.112,1,1958), and S.Takeda and M.Roux (J.Phys.Soc.Japan 16,No.7,1961), and discussed by S.J.Buchsbaum and S.C.Brown (Phys.Rev.106,196,1957). This consists in measuring the attenuation and phase shift of TE_{10} waves in a rectangular waveguide traversed in the direction of the electric field by a small tube containing the plasma. The application of this method is limited by the skin effect. This diagnostic technique was employed to investigate recomination in neon plasma. The plasma was contained in a 3 mm dia-

Card 1/ 2

ACCESSION NR: AP4040295

meter tube at a pressure of 3.3 mm Hg and was excited by 10 microsec current pulses of 3 or 4 amp. Microwaves of 3.2 cm wavelength were employed in 1 microsec pulses. The attentuation was measured by a substitution method, and the phase shift was obtained from the shift in the position of standing wave nodes. How the nodes were located during the 1 microsec pulses is not disclosed. The recombination was found to take place considerably more slowly than calculated by the theory of V.L.Granovskiy (ZhETH 13,123,1943). Similar results have been obtained by G.N.Zastenker and YeF.Gubochkina (Voprosy* radioelektroniki, GKRE, No.6,1961). The discrepancy is ascribed to rapid loss of electron energy by collisions of the first kind. The agreement with theory was improved by calculating the energy lost by the electrons to gas molecules from the experimental values of E/p and employing this in the theoretical calculations of electron densities and temperature. Strength of concrete setting in cold weather. S. A. Mironov and V. N. Sizov. *Stroitel. Prom.* 32, No. 9, 9–12 (1954); cf. *C.A.* 48, 6005*b*.—Specimens with 5–20% $CaCl_2$ or 5–20% NaCl were held at −10° to −20° for up to 180 days and tested after a 6–7-hr. thawing at 15°. Strength increase with time of salt-bearing concretes is slower than in conventional concrete. Salt concn. must be adjusted to temp.; otherwise the setting is slowed down. Setting at −23°, −20°, −15°, and −10° is achieved by adding, resp., 18, 14, 8, and 3% $CaCl_2$ in combination with 5–7% NaCl. Such concretes reach at these temps. 25% of their strength in 7 days and 50–80% after 28 days. The water-cement ratio should be held at 0.45–0.70, being 8–10% less than in plain concrete.

V Concretes setting in the cold. V. N. Sizov. *Stroitel. Prom.* 33, No. 9, 30–3(1955).—Since strength increase of concrete is greater at −20° when a mixt. of $CaCl_2$ and NaCl is used, expts. were conducted in which the total amt. of salt added was the same but the proportions of the components were varied. More than 5% NaCl is not desirable. NaCl helps the setting at low temps. while $CaCl_2$ improves the strength of concrete on aging. Optimum proportions recommended for use were $CaCl_2$ 3 + NaCl 7, $CaCl_2$ 9 + NaCl 6, and $CaCl_2$ 15 + NaCl 5% if the lowest temp. during the first ten days might be −10, −15, or −20°, resp. The undesirable effect of large salt addn. can be reduced by replacing $CaCl_2$ with NaF, KOH, $CaCO_3$, or $NaNO_2$ which can replace about the double amount of $CaCl_2$ when combined with 5% NaCl and even larger proportions when more NaCl is used, particularly in combination with NaF. For pouring concrete at freezing temps. while using preheated materials, addn. of NaF 1.5 + NaCl 5, NaF 2 + NaCl 7, and NaF 2.5 + NaCl 9% is recommended for −10, −15, and −20°, resp.

AUTHOR: Sizov, V. N. Doctor of Technical Sciences

TITLE: The Correct Way of Concreting in Winter. (Pravil'no proizvodit' zimneye betonirovaniye).

PERIODICAL: Beton i Zhelezobeton, 1957, Nr.9. pp.339-343 (USSR)

ABSTRACT: In the northern and eastern part of Soviet Russia concreting is carried out when the temperature is down to - 40°C and in conditions of permanent frost. The main technical publications dealing with this problem are: "Technical conditions for carrying out and taking over Building and Assembly Work" (TU 112-55), and "Instruction on Carrying out Concreting Work in Industrial and Residential Buildings During Winter", published 1954. It is necessary to protect concrete during initial hardening until the concrete reaches 50% of its final strength, i.e. 50 kg/cm² when the mark of concrete is lower than 100. The effect of frost before this stage not only lowers the concrete's strength, but also affects adversely the adhesion to reinforcement. Concrete so affected, could be loaded only to 60 or 70% of its calculated strength. The striking of formwork should take place only when the hardness of the concrete reaches 50% of the final hardness (28 days). When

Card 1/5

concrete articles are steam-cured no clinker or pozzolana cement should be used. Nor should these two types of cement be used when, during concreting, the temperatures of the soil is higher than that of the surrounding air. With steam-curing at a temperature not lower than 60°C, and especially at 85/90°C, these two types of cement can be more effectively used in reinforced concrete constructions than Portland cement. The mineralogical content (e.g. the content of tri-calcium silicate and of tri-calcium aluminate), activity, and speed of hardening of the cement, are of primary importance. Cements with a content of more than 45-55% of C_3S form the bulk of cement production today. Acceleration of the hardening of concrete can be achieved by the addition of calcium chloride, by the reduction of the water/cement ratio, by increasing the gypsum content, by re-grinding of the cement, and finally by heat-curing. Of great importance for the rationalisation of building during winter is the wide application of pre-fabricated reinforced units. Experience gained by Zaporozhstroy, Krivorozhstroy and other building organizations shows that pre-cast units can be manufactured quite conveniently on concrete yards during winter. Magnitostroy and Chelyabmetallurgstroy

The Correct Way of Concreting in Winter.

have manufactured a large amount of pre-cast foundations and other structural elements during the winter by the use of electrical heating. When using rapid-hardening cement and concrete the temperature of the heating may be lower and of shorter duration. A handbook covering the processes of steam-curing of pre-cast constructions is: "Instructions on Steam-Curing Concrete and Reinforced Concrete Products in Factories and Concrete Yards" (I 206-55 MSPMKhP). In comparison with the steam-curing of concrete without $CaCl_2$, steam-curing of reinforced concrete with 2% additive of calcium chloride somewhat increases corrosion of the reinforcement. This increased corrosion does not affect the load-bearing capacity of the reinforcement if the protective layer of concrete is at least 15 mm. Calcium chloride should not be used when the heat-cured concrete constructions are from clinker or slag, as the danger of corrosion arising from poorly burned clirker is considerably increased. The addition of calcium chloride to a concrete mix at a temperature not exceeding 20°C increases the plasticity of the mix, as $CaCl_2$ is a plastifying agent. The assembly of pre-cast units during winter conditions

Card 3/5

The Correct Way of Concreting in Winter. 97-57-9-1/17

depends on the way the joints are made. Grouting of joints by concrete mix or grout, and their heat-curing, is extremely complicated and difficult; therefore, the use of frost-resistant and anti-corrosive mixture appears to be the best solution of forming joints in heavy frost. A handbook describing grouting of joints is: "Instructions on Assembly of Reinforced Concrete Units", published 1957. It is advisable to form concrete foundations by using concrete of high relative strength and by pre-heating (electrically) for 8-10 hours up to a temperature of 40 - 50°C. Electrical heating or pre-heating is generally done by a current of 50-110 V, but 120 - 220 V (standard voltage) may also be used. The electrical heating should follow the instructions given in "Instructions on Electro-heating of Reinforced Concrete and Masonry" (I 94-54 MSPMKhP). Of considerable practical interest is the successful solution of the problem of concrete hardening at low temperatures by the use of anti-frost additives. These concretes are usually prepared by using pre-heated material (aggregate sand), and after concreting the heating is kept on for one or two days. The hardening takes place at a temperature

Card 4/5

The Correct Way of Concreting in Winter. 97-57-9-1/17

of up to -10°C without loss of final strength. Concrete made with increased additives of various salts (up to 20%) is prepared from cold materials (aggregate sand) and hardened at a temperature of up to -20°C. When using various additives of salts the instructions given in the following publication should be observed: "Temporary Instructions for the Preparation of Concrete with Salt Additives, and its Hardening During Frost" (I 207-55 MSPMKhP). The Academy of Building and Architecture of USSR, (Akademii stroitel'stva i arkhitektury SSSR), together with the Institute for Concrete and Reinforced Concrete (Institut betona i zhelezobetona), is carrying out research and tests on the behaviour of concrete during various climatic conditions.

ABSTRACT: The following book is reviewed: A.G. Sarapin, "Production of Large-Scale Reinforced Concrete Constructions and Details Using "Stand" Method', published by Gosstroyizdat, 1958. It deals with Russian and Foreign problems of and research into the production of large precast reinforced concrete units. There is an interesting chapter compiled by the author in conjunction with operatives of the laboratory for reinforced concrete products of the Institute of Building Technique of the Academy of Architecture of USSR (Institut stroitel'noy tekhniki Akademii arkhitektury SSSR). Curing methods are criticised. In general the review is favourable.

TITLE: Methods of Obtaining High-Strength Vibrated Concretes Using Short Heat Curing (Sposoby polucheniya vysokoprochnykh betonov dlya vibroprokata pri kratkovremennoy teplovoy obrabotke)

PERIODICAL: Beton i Zhelezobeton, 1959, Nr 1, pp 4-10 (USSR)

ABSTRACT: N.Ya. Kozlov, together with collectives SKB, NIIMosstroy and the Kalibrovskiy experimental plant investigated and solved problems in the manufacture of panels using ordinary reinforcement. Complications arise in the manufacture of prestressed panels when vibration is used for consolidation. The Giprostroyindustriya, under the leadership of Engineer A.A. Susnikov, put forward to Gosstroy of USSR and the Institute for Concrete and Reinforced Concrete, ASiA SSSR (Instituta betona i zhelezobetona. ASiA SSSR), a programme to work out

Card 1/6 compositions of concrete and ways of heat curing for

Methods of Obtaining High-Strength Vibrated Concretes Using Short Heat Curing.

prestressed reinforced concrete panels using vibration for consolidation. For the manufacture of panels reinforced with ordinary reinforcement and consolidated by vibration, a cement-sand mix of 1 : 2 (by weight) should be used and panels cured for 2 hours on the conveyor belt or in forms at a temperature of 100°C. Special treatment is required in the case of prestressed reinforcement when the minimal strength of concrete must not be lower than 210 kg/cm^2 for the release of tensioned reinforcement. Portland cement used should be of high alumina content, ground to 3 500-5 000 cm^2/g (according to Tovarov). Classified or coarse pure sand should be used with the addition of granite aggregate up to 10 mm in size. Heat curing should be carried out at a temperature of 100°C for a period of 3 hours (including the period of raising and lowering of temperature). It is necessary during the curing to preserve the degree of humidity. Rapid hardening

Card 2/6 cements of a strength of 300 kg/cm^2 are being manufactured.
